

OEHHA's New Hot Spots Exposure and Assessment Guidelines

October 24, 2012

Steve Hill
Sierra Research

Introduction

- Background
- Changes in Cancer Risk Methodology
 - ❖ Age-Specific Factors
 - ❖ Short-term Breathing Rates
 - ❖ Duration of Exposure
 - ❖ Activity Patterns
 - ❖ Spatial Averaging
- Bottom Line

Background

Background:

What is this document for?

- Technical basis for subsequent guidance to preparers of Hot Spots Health Risk Assessments (HRAs).
- Guidance is also used in toxics new source review programs throughout California
- Risk assessments are often include in California Environmental Quality Act (CEQA) documents

Background:

What does this document contain?

- For point estimate (single value) cancer risk assessments
 - ❖ Mandatory methodology for all HRAs prepared for Hot Spots program
 - ❖ Default values for some variables.
 - ❖ Recommendations for some variables
- For stochastic analysis for cancer risk (optional for Hot Spots risk assessment)
 - ❖ Mandatory methodology for stochastic analysis prepared for Hot Spots program
 - ❖ Default ranges for variables.

Background:

What is the Hot Spots Program?

- AB2588, the “Air Toxics ‘Hot Spots’ Information and Assessment Act of 1987”
- Requires facilities to report emissions of Toxic Air Contaminants
- Requires “High Priority” facilities to prepare Health Risk Assessments
 - ❖ Cancer
 - ❖ Chronic non-cancer
 - ❖ Acute non-cancer
- Requires notification to neighbors in case of significant risks
- Risk Reduction

Background: What is a Risk Assessment?

- Risk Assessment Components
 - ❖ Exposure Assessment
 - Emissions
 - Dispersion Modeling
 - Receptor Characterization
 - ❖ Hazard Assessment
 - Dose
 - Toxicity
 - ❖ Reporting/Notification

Background:

Why is the Guidance being revised?

- Last updated in 2000[†]
- Office of Environmental Health Hazard Assessment (OEHHA) is required by state law to consider infants and children
 - ❖ OEHHA has developed factors to address early-in-life exposures
- Incorporate the latest scientific data on exposures, fate, and transport
 - ❖ Large body of literature published since last version

[†]OEHHA revised breathing rate guidance in 2008.

Background:

What is being revised?

- Inhalation Pathway
 - ❖ Age-specific values for breathing rate, susceptibility
 - ❖ New short-term breathing rates for periodic exposures
 - Take level of activity into account
 - ❖ Duration of Exposure
 - Residential
 - Worker
 - ❖ Activity Patterns
 - ❖ Spatial Averaging
- Dermal Exposure
 - ❖ Several values combined into a single value

Background: What is being revised?

- Exposure duration for short term projects
- Noncancer Assessment Unaffected
 - ❖ Acute and chronic noncancer health impacts based on Reference Exposure Levels (RELs)

Cancer Risk

Cancer Risk: Tiered Risk Assessment Approach

- Tier 1: Point Estimate using default values for variates (high-end values for 2 dominant pathways; average for others)
- Tier 2: Point Estimate using justified site specific values
- Tier 3: Stochastic approach using OEHHA default distributions
- Tier 4: Stochastic approach using justified site specific distributions

Cancer Risk: Sidebar on SB-352

- SB-352 requires risk assessment (“reverse” risk assessment) for proposed school site within 500 feet of a busy roadway.
 - ❖ Other existing state law requires identification and assessment of air pollution sources within ¼ mile
- SB-352 specified use of the Hot Spots risk assessment procedures, but current guidance only specifies 24-hour breathing rates
- 1-hour breathing rates at various levels of activity have been added for use in SB-352 risk assessments.

Cancer Risk: Pathways

- Inhalation
- Non-inhalation (due to deposition)
 - ❖ Dermal
 - ❖ Soil Ingestion
 - ❖ Mother's Milk
 - ❖ Home Grown Produce
 - ❖ Home Raised Meat
 - ❖ Angler Caught Fish
 - ❖ Cow's Milk
 - ❖ Drinking Water (Not reservoirs)

Cancer Risk: Pathways

- Initial screen to identify dominant pathways for inclusion in Risk Assessment
- Inhalation
- Other Pathways
 - ❖ Soil Ingestion
 - ❖ Mother's Milk
 - ❖ Dermal
 - ❖ Other

Cancer Risk: Exposure variates for different age ranges

- Old methodology for residential risk:
 - ❖ Risk = Dose * Potency
- New methodology for residential risk:
 - ❖ Risk = Dose_{prenatal} * 10 * 0.33/70 * Potency PLUS
 - Risk = Dose₀₋₂ * 10 * 2/70 * Potency PLUS
 - Risk = Dose₂₋₁₆ * 3 * 14/70 * Potency PLUS
 - Risk = Dose₁₆₋₃₀ * 1 * 14/70 * Potency

Exposure (i.e., Daily Dose) is greater early in life because of behavioral and physiological differences.
Susceptibility is greater as well.

Cancer Risk: Exposure variates for different age ranges

- $\text{Dose}_{\text{inhalation}} = \text{concentration} * \text{breathing rate}$
 - ❖ Old method: used 80th percentile breathing rate[†]
 - ❖ New method: Use high-end breathing rates for each age range

[†]Interim guidance in 2008 changed from 95th to 80th percentile

	3 rd Tri- mester	0 < 2 yrs	2 < 16 yrs	16 < 30 yrs	30 < 70 yrs
	L/kg/day				
Mean	225	658	452	210	198
95 th	361	1090	745	335	295
Current				Ages 0-70	302

Cancer Risk: Breathing Rates

- Chronic periodic exposure
 - ❖ For exposure only during 8-12 hours/day
 - Off-site workers
 - Schools
 - Residential exposure to single-shift emissions
 - ❖ Previous method: Dose adjusted to account for overlap between emissions and receptor
 - ❖ New method: Also account for 8-hour breathing rates at various activity levels

Cancer Risk: Exposure Duration

- Residential exposure
 - ❖ Old methodology:
 - 70-year exposure duration (lifetime risk)
 - ❖ New methodology:
 - 30-year exposure duration (residential risk)
 - Represents 95th percentile for actual residence at a single location
 - Lifetime risk still calculated for use in burden calculations

Cancer Risk: Exposure Duration

- Worker Exposure
 - ❖ Old methodology:
 - 40-year employment tenure
 - ❖ New methodology:
 - 25-year employment tenure
 - Represents 95th percentile
 - 8-hour breathing rate
 - Guidance not clear on when to use this

Cancer Risk: Activity Patterns

- Old methodology:
 - ❖ No Adjustment
- New methodology:
 - ❖ Ages 0<2 0.86[†]
 - ❖ Ages 2<16 0.72[†]
 - ❖ Ages 16<70 0.73

[†] Facilities with a school within the 1 X10⁻⁶ residential risk cancer risk isopleth should use 1 as the fraction of time at the residence for ages 3rd trimester to less than age 16.

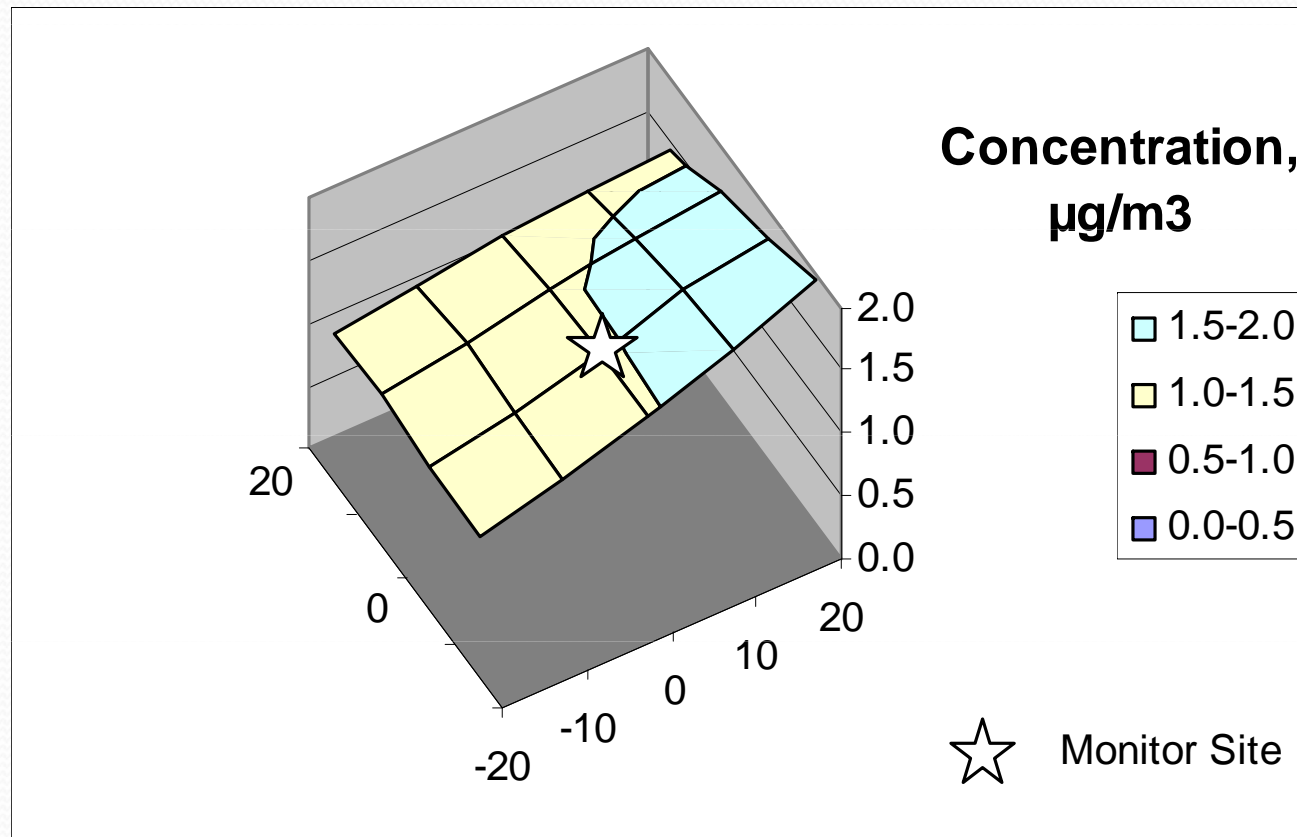

Cancer Risk: Spatial Averaging

- Old methodology:
 - ❖ No Adjustment
- New methodology:
 - ❖ Use average of modeled concentrations within a 20 m x 20 m grid

May be useful for very short stacks with very close receptors (e.g., gasoline dispensing facilities or diesel backup generators)

Cancer Risk: Spatial Averaging

Cancer Risk: Short-term projects

- Old methodology:
 - ❖ Varied by jurisdiction
- New Methodology
 - ❖ Residential exposure durations start with exposure in the 3rd trimester and use age sensitivity factors.

Cancer Risk: Short-term projects

- New methodology:

- ❖ < 2 months duration: no cancer risk

- ❖ 2-6 months duration: assume 6 months exposure

- Risk = Dose_{prenatal} * 10 * 0.33/70 * Potency PLUS
Risk = Dose₀₋₂ * 10 * 0.33/70 * Potency

- ❖ > 6 months duration: exposure = project duration (up to 30 years)

- Risk = Dose_{prenatal} * 10 * 0.33/70 * Potency PLUS
Risk = Dose₀₋₂ * 10 * 2/70 * Potency PLUS
Risk = Dose₂₋₁₆ * 3 * 14/70 * Potency PLUS
Risk = Dose₁₆₋₃₀ * 1 * 14/70 * Potency

Cancer Risk: Short-term projects

- Example: 30 month project
 - ❖ Old methodology
 - Some jurisdictions: any project over a threshold period (e.g., one year) treated as permanent. Use lifetime risk to evaluate cancer impact
 - Some jurisdictions: Short-term projects evaluated using a specified (e.g., 9 years) duration.
 - ❖ New methodology
 - Risk = Dose_{prenatal} * 10 * 0.33/70 * Potency PLUS
 - Risk = Dose₀₋₂ * 10 * 2/70 * Potency PLUS
 - Risk = Dose₂₋₁₆ * 3 * 0.33/70 * Potency

What is the bottom line?

The Bottom Line: Residential Risk

- Individual risk is calculated using 30-year exposures.
- Changes in early-in-life potency factors, exposure duration, and activity patterns increase individual risk (over previous method) by about 7% if a school is present in the impact area,[†] decrease by 13% if not.
- Changes in breathing rates, however, combined with the above, result in an increase in individual risk by a factor of 2.7 if a school is present,[†] or 2.2 if not.

[†]The impact area is the area within the 10^{-6} isopleth, using the 30-year exposure methodology and no activity adjustment.

The Bottom Line: Population Risk

- No change from previous guidance
 - ❖ OEHHA recommends reporting the number of individuals residing within a 1×10^{-6} , 1×10^{-5} , 1×10^{-4} residential risk isopleth.
 - ❖ Cancer burden calculated using 70-year exposure (not 30-year exposure)

The Bottom Line: Worker Risk

- Changes in exposure duration reduce worker risk by 37%.

The Bottom Line: Short-term Projects

- < 2 months: no cancer risk
- 2-6 months: assume 6 months exposure
- > 6 months: exposure = project duration (up to 30 years)

Residential exposure durations start with exposure in the 3rd trimester and use age sensitivity factors.

Next Steps

- OEHHA will incorporate the Technical Support Document methodologies into its Risk Assessment Guidelines
- California Air Resources Board will incorporate the Guidelines into Hot Spots Analysis Reporting Program (HARP)

Summary

- Residential risks using the new methodology will be much higher (much, much higher for short-term projects in some jurisdictions)
 - ❖ Age-specific breathing rates increase the risk
 - ❖ Age-specific sensitivity factors increase the risk
 - ❖ Duration of residential exposure reduces the risk
 - ❖ Activity pattern factor may reduce the risk
- Worker risks will go down
- Noncancer impacts not affected
